# GTS documentation

## What is GTS?

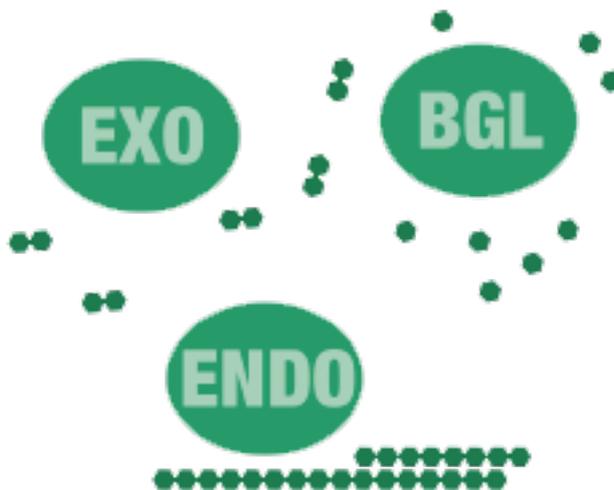

GTS (Glucose Tolerance Signature) is a method to propose mutations for  $\beta$ -glucosidase enzymes used in Second-Generation Biofuel production. GTS uses structural signatures to detect patterns, which can improve the activity of non-tolerant  $\beta$ -glucosidases, based on a manually curated database of glucose-tolerant  $\beta$ -glucosidases.

## Second-Generation Biofuel problem

Second-Generation Biofuel is produced by residues obtained from the first generation biofuel production. They can be obtained from biomass, such as corn, algae, sugarcane, and so on. The production process is based on the extraction of fermentable sugars from cellulose.

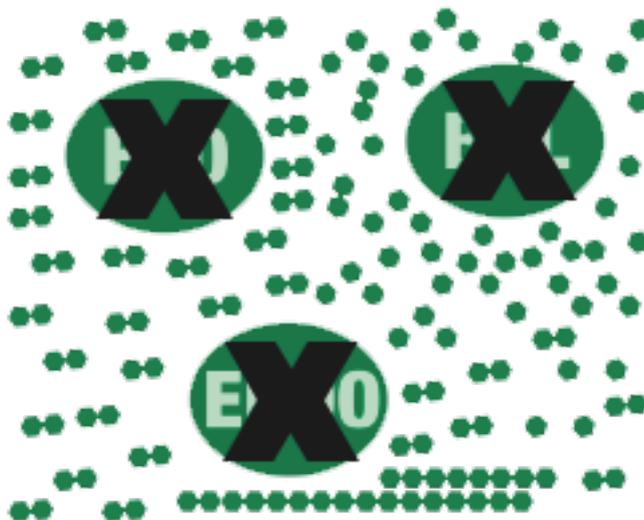

Cellulose is decomposed by the action of three enzymes: endoglucanases, exoglucanases, and  $\beta$ -glucosidases. Endoglucanases act first, cleaving cellulose in oligosaccharides of several lengths. Then, exoglucanases cleave the oligosaccharides in disaccharides, such as cellobiose. In the end, beta-glucosidases cleaves the cellobiose in two molecules of glucose, that will be used in the fermentation process for obtain biofuel.

$\beta$ -glucosidases are strongly inhibited by high glucose concentrations (same used for biofuel production).

In addition, it increases cellobiose concentration that inhibits endoglucanases and exoglucanases.

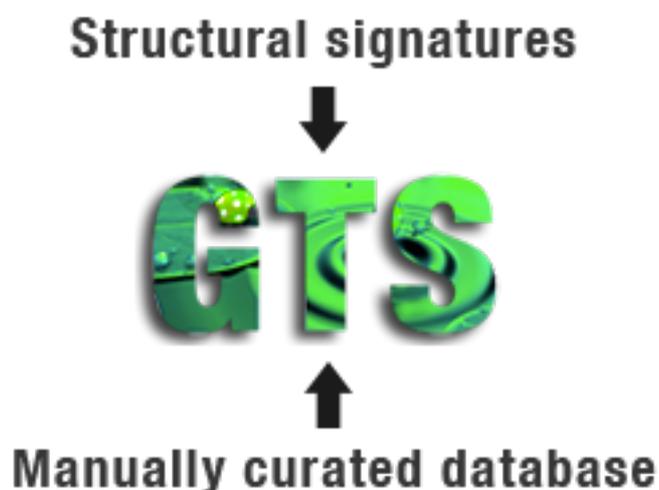

**Glucose-tolerant  $\beta$ -glucosidases:**  $\beta$ -glucosidases of high resistance to glucose inhibition, also called glucose-tolerants, can help to improve the biofuel production. Also, some mutations can turn non-tolerant in glucose-tolerant  $\beta$ -glucosidases.

## How GTS method Works?

GTS method constructs structural signatures for wild and mutant proteins and compares the signature's variation with a manually curated database of glucose-tolerant  $\beta$ -glucosidases, called **Betagdb** (available at <http://bioinfo.dcc.ufmg.br/betagdb>).

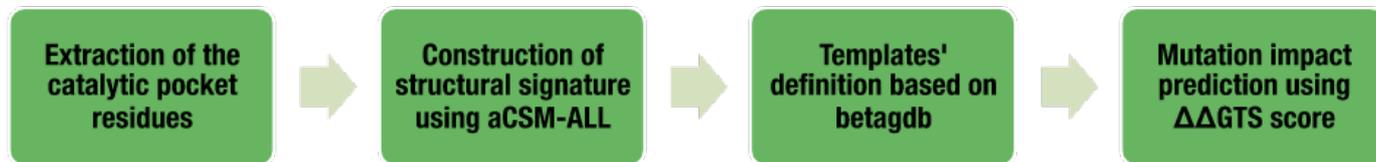

## Inputs

GTS requires three beta-glucosidases:

1. Wild beta-glucosidase
2. Mutant beta-glucosidase

### 3. Template beta-glucosidase

#### GTS steps

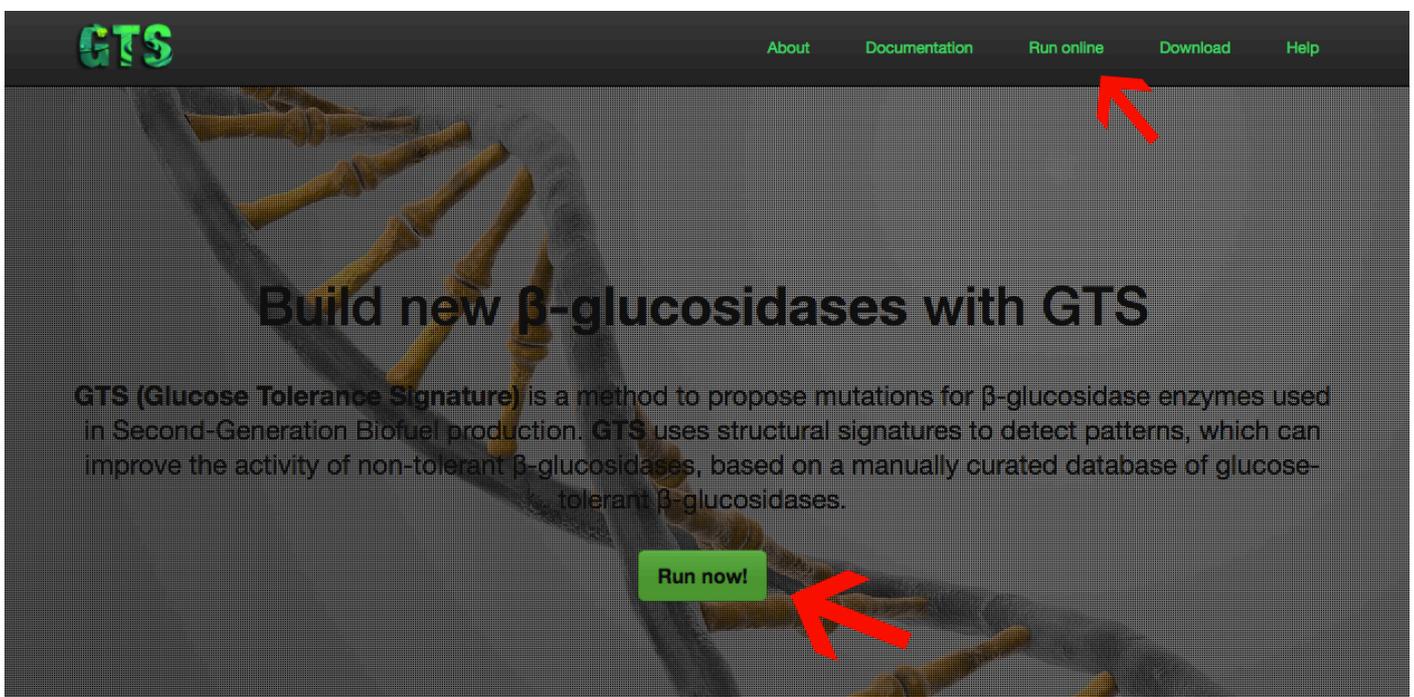

1. The first step is the extraction of the catalytic pocket residues. The mutant and wild protein are aligned with 3VIK, the only beta-glucosidase in complex with cellobiose detected in the literature. The residues of the catalytic pocket of 3VIK are known: Q45, H148, W149, N192, S193, L195, T196, D199, M207, N253, I254, N255, Y273, N335, F336, Y337, T338, L340, W374, E402, W444, E451, W452, and F460. We performed alignments using MultiProt (<http://bioinfo3d.cs.tau.ac.il/MultiProt>);
2. Then, we constructed structural signatures using aCSM-ALL. We used cutoff ranging of 0Å until 10Å, and step distance of 0.1Å;
3. We previously calculated the signature of 23 glucose-tolerant beta-glucosidases of betagdb. We calculated the distance among all glucose-tolerant beta-glucosidase and wild and mutant. The lowest values correspond to the templates;
4. We calculated the distance between wild and its template ( $\Delta GTS_{Wt}$ ), and mutant and template ( $\Delta GTS_{Mt}$ ). The difference between both distances is the variation of the signature variations ( $\Delta \Delta GTS$ ).

# Running online

Running online is the best way to execute GTS. It is available online at: <<http://bioinfo.dcc.ufmg.br/gts>>.

## Accessing the “Run online” panel

Click in “Run online” or in the “Run now!” Button.

The “Run online” panel requires some information to execute:

- **Project name:** define a name for your project. You can use any name (the system will create an unique ID for each project);
- **E-mail:** declare your e-mail (optional);
- **Mutation evaluated:** insert the point mutation or multiple mutations evaluated (optional);
- **Wild PDB:** input the wild PDB file;
- **Mutant PDB:** input the mutant PDB file.

## Run online

**Project name:**  
Define a name for your project (required)

**E-mail:**  
Receive the results in your e-mail (optional)

**Mutations evaluated:**  
E.g. E96K (optional)

**Wild PDB (required):**  
Escolher arquivo Nenhum arquivo selecionado

**Mutant PDB (required):**  
Escolher arquivo Nenhum arquivo selecionado

**Limit: 2MB. Please, send only one chain.**

[Download sample dataset](#)

**Submit**

We made available a database with 27 mutations evaluated in the paper. We can download the database and perform analysis using GTS online. We also made available a table with expected values and the values found.

15	w15.pdb	m15.pdb	N273V	$\Delta\Delta\text{GTS} > 0$	-55.26

## Running an example (H228T)

Now, we will run the first example of that database. The mutation H228T, where detected for a non-tolerant beta-glucosidase and improved its glucose tolerance. For these reason, we expected a  $\Delta\Delta\text{GTS}$  negative.

# Run online

<p><b>Project name:</b></p> <input type="text" value="Bgl1B_mutation_H228T"/>	<p><b>Wild PDB (required):</b></p> <p>Escolher arquivo   w1.pdb</p>
<p><b>E-mail:</b></p> <input type="text" value="diego@dcc.ufmg.br"/>	<p><b>Mutant PDB (required):</b></p> <p>Escolher arquivo   m1.pdb</p> <p>Limit: 2MB. Please, send only one chain.</p>
<p><b>Mutations evaluated:</b></p> <input type="text" value="H228T"/>	<p><a href="#">Download sample dataset</a></p>

After submit the data, GTS online will process your requisition. A unique ID will be created for your project. When the process to finish, you can click in the button "Show results".

In the right, it is showed visualizations of the wild protein. We also highlighted the protein pocket and its residues.

Below, we showed a visualization of the mutant protein. We also highlighted the protein pocket and its residues.

# Run by scripts

We made available the scripts to run GTS. However, we cannot have sure that you will be able to reproduce the software environment. If you have problems, run the online version.

**We strongly recommend running GTS online.**

## Requirements

- O.S. Linux 64bit (recommended Ubuntu 16.04)
- Python (version 2)
- Library Numpy
- Perl
- aCSM
- MultiProt

## Scripts

Script	Input	Output
extractSite.py	PDBs files inserted in the folder "pdb".	PDBs files with the catalytic pocket extracted.
aCSM.pl	List with address of PDBs files with the catalytic pocket extracted.	CSV file with total of atoms in the cutoff distances.
dgts3.py	CSV file obtained from aCSM. The first 23 lines must represent the beta-glucosidases from betadb in alphabetical order.	$\Delta\Delta$ GTS and templates for wild and mutant save in the file "result.txt".
